## Introduction

- The phase 3 PARADIGM trial (NCT02394795) met the primary endpoint, demonstrating the superiority of first-line panitumumab in combination with modified FOLFOX6 (mFOLFOX6) vs bevacizumab in combination with mFOLFOX6 in the left-sided and overall RAS wild-type (WT) metastatic colorectal cancer (mCRC) populations<sup>1</sup>
- Left-sided population: median overall survival (mOS), 37.9 vs 34.3 months; hazard ratio (HR), 0.82 (95.798% CI: 0.68–0.99); P=0.031
- Overall population: mOS, 36.2 vs 31.3 months; HR, 0.84 (95% CI: 0.72–0.98); P=0.030
- Right-sided population (exploratory endpoint): mOS, 20.2 vs 23.2 months; HR, 1.09 (95% CI: 0.79–1.51)
- The PARADIGM biomarker study (NCT02394834) was designed to investigate potential biomarkers related to primary and secondary resistance of each therapy by using tumor tissue and circulating tumor DNA (ctDNA)
- In this analysis, we evaluated the usefulness of negative hyperselection by gene alterations in ctDNA related to primary resistance to anti-epidermal growth factor receptor (EGFR) therapy in patients enrolled in the PARADIGM biomarker study

## Methods

gression, unacceptable toxicity, withdrawal of consent, investigator's judgement, or curative intent resection; Primary tumor in descending igmoid, and rectum; <sup>c</sup>Patients with available ctDNA among those included in efficacy analysis set in the PARADIGM study bhoma kinase; Amp, amplification; BRAF, v-raf murine sarcoma viral oncogene homolog B1; DCR, disease control rate; DOR, duration xtracellular domain; ECOG, Eastern Cooperative Oncology Group; ETS, early tumor shrinkage; HER2, human epidermal growth factor receptor 2; MET, mesenchymal epithelial transition factor receptor; NGS, next-generation sequencing; NTRK1, neurotrophic tyrosine receptor kinase 1; PFS progression-free survival; *PTEN*, phosphatase and tensin homolog; R, randomization; R0, margin-negative resection; *RET*, rearranged during transfection; RR, response rate; WT, wild-type

- Baseline plasma ctDNA (>10 ng/mL and >10 nM DNA) from patients enrolled in the biomarker study was assessed using a custom panel (PlasmaSELECT-R 91, PGDx)
- The panel was designed to detect mutations, amplifications, and rearrangements in 90, 26, and 3 mCRC-related genes, respectively, as well as microsatellite instability Targeted genomic regions spanned 250 kb
- Prespecified gene alterations for hyperselection that have been reported to confer resistance to anti-EGFR antibody therapy included KRAS, NRAS, BRAF (V600E), PTEN, and extracellular domain EGFR mutations, HER2 and MET amplifications, and ALK, RET, or NTRK1 fusions<sup>2-5</sup>
- Hyperselection status (all negative vs gene altered [any positive biomarker]) was correlated with OS, PFS, and RR in the PARADIGM study population

## Acknowledgments

We thank the patients, their families, and their caregivers; the PARADIGM investigators and their team members at each study site; and colleagues from Takeda Pharmaceutical Company Limited. Professional medical writing was provided by Kalpana Vijayan, PhD, and Lauren Gallagher, RPh, PhD, of Peloton Advantage, LLC, an OPEN Health company, Parsippany, NJ, USA, and funded by Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited. The study was sponsored by Takeda Pharmaceutical Company Limited.

# Results

- ctDNA status was evaluable in 91% (733/802) of patients (Figure 2; Figure 3) 28% of patients had at least 1 gene alteration

Hyperselected • Overall, n=258<sup>a</sup> • Left-sided, n=221 (85.7%) • Right-sided, n=35 (13.6%)

QC, quality control

shown in **Table 1**

- 72% of patients had no gene alterations and were classified as hyperselected

#### When stratified by primary tumor sidedness, any gene alteration was detected in 21% of patients with left-sided mCRC and 50% of patients with right-sided mCRC

<sup>3</sup>Some patients had multiple primary lesions in both the left and right side

 Baseline characteristics of patients who were hyperselected or had gene alteration within each treatment arm and across left- and right-sided mCRC populations are

 The OncoPrint profile of mutational frequencies and types of alterations of the 10 denes sequenced are shown in Figure 3

◄ ► Bevacizumab better Panitumumab better

tumor sidedness in patients with any of these gene alterations Negative hyperselection using ctDNA analysis rather than tumor sidedness may identify appropriate patients for first-line panitumumab over bevacizumab

OS was similar or inferior with panitumumab vs bevacizumab regardless of the primary

These results warrant further validation in additional cohorts
